#### Naturalistic expository discourse processing in school-aged children and adults Maxime Tulling<sup>1</sup>, Suhail Matar<sup>1</sup>, Ellie Abrams<sup>1</sup>, Ria Mai Geguera<sup>1</sup>, Miriam Hauptman<sup>1</sup>, Alicia Parrish<sup>1</sup>, Sarah F. Phillips<sup>1</sup>, & Liina Pylkkänen<sup>1,2</sup> NYU NSF Grant BCS-1923144 1. New York University | 2. NYUAD Research Institute Introduction Go to: Grasping the larger meaning of discourse is crucial for academic success in Introduction the classroom Goal & Questions □ However: Stimuli & Procedure Only few studies investigated the neural architecture involved with Coding discourse processing in typically developing children<sup>[1]</sup> Model & Analysis Most naturalistic discourse processing studies use event and character-Poster formatted oriented narratives, rather than topic-oriented expository discourse for electronic viewing encountered in classrooms

❑ While NARRATIVE DISCOURSE seems to rely on the right hemisphere to establish coherence across sentences<sup>[1,2]</sup>, studies investigating EXPOSITORY DISCOURSE found no such effects<sup>[3,4]</sup>

### Goal and Questions

To gain a deeper understanding of the neural architecture of naturalistic expository discourse processing we model local and global operations involved in establishing discourse coherence across both hemispheres, and establishing their relative temporal dynamics

**Q1**: Which predictors of discourse explain MEG data acquired during expository processing?

- Q2: Is there any hemispheric dominance involved in establishing discourse coherence?
- Q3: Does lateralization and sensitivity of discourse complexity interact with age?

# Stimuli and Procedure

- □ Partial sample of 11 adults (M=31.2, SD=11.8, range=19-53) and 7 children (M=8.6, SD=1.35, range=7-10)
- Listened to 4 three-minute audio segments (YouTube: <u>SciShow Kids</u>)
  - $\rightarrow$  teaching about the human body (i.e. the brain, sleep, goosebumps and dizziness)
- □ 1 kHz Magnetoencephalography (MEG) data; 157 channels; bandpass 0.1-200 Hz
- □ Independent Component Analysis (ICA) applied to filter known noise sources → e.g. eyeblinks and heartbeats
- Data downsampled by a factor of 10

# Coding

All stories were annotated for various linguistic predictor variables (Figure 1A)

- CONTROL VARIABLES: acoustic, phonetic, lexical and syntactic
- DISCOURSE VARIABLES: local operations (Figure 1B) and global complexity (Figure 1C)

A. Linguistic Predictor Variables

B. Example Local discourse variables

# Model and Analyses

□ All stories were annotated for various linguistic predictor variables (Figure 1A)

- CONTROL VARIABLES: acoustic, phonetic, lexical and syntactic
- DISCOURSE VARIABLES: local operations (Figure 1B) and global complexity (Figure 1C)
- Data from each MEG sensor is modeled as a sum of all predictors, each passed through its own linear system (modeled as a temporal response function, or TRF; Figure 2)<sup>[5,6]</sup>.
- For the left and right sensor space, we use regularized regression to compute the TRFs that best explain the data for each sensor, then find the latencies at which each predictor of interest significantly contributes to the model fit

Figure 2 Main analysis method. For each sensor (left), data are regressed against predictors and corresponding TRFs.

#### Summary

- Using a combination of high temporal resolution MEG recordings, naturalstic speech and a model-based analysis, we aim to investigate the lateralization of establishing discourse coherence in adults and children.
- □ Project still in sandbox phase, any comments or suggestions are much appreciated!
